

PROPOSAL · NATURE'S JOY HERBAL COSMETICS

PulseCommerce

Customer intelligence and WhatsApp campaigns for your
WooCommerce store — built on infrastructure you own, with
no per-message fees.

Executive summary

Setups Works proposes to deliver **PulseCommerce**, a private analytics platform for the Nature's Joy WooCommerce store.

WooCommerce reports on orders. It does not report on customers, cohorts, marketing channels, or stock risk. That leaves a set of questions unanswered that directly affect revenue: which customers are worth keeping, which have quietly stopped buying, where new customers actually come from, which products are about to run out, and what next month is likely to look like.

PulseCommerce answers those questions from your existing order data, without adding load to the storefront, without copying customer records to a third party, and without anyone modelling a database first. It also closes the loop: an audience identified in the platform can be messaged on WhatsApp from the same screen, through a gateway Nature's Joy owns.

That messaging need not be manual. A sequence can be set to run itself over days — a reminder, then a discount, then a last note — with customers joining as they qualify and leaving the moment they buy. In the other direction, a customer who writes to the business out of hours is answered straight away rather than waiting until morning.

This document sets out the proposed scope, how the platform connects to your store, what is delivered, and commercial terms. Two routes are offered: ₹35,000 once with a private WhatsApp gateway and no per-message cost, or ₹25,000 once with Meta's official Cloud API and roughly ₹10,000 a month in message charges thereafter.

The opportunity

What is visible today

The WooCommerce admin shows gross sales by date, a list of top products, and a handful of counts. It is transaction-centric by design: it reports on orders, not on the people placing them.

What is not visible

Questions a growing store needs answered, none of which WooCommerce reports:

On customers

- Which customers generate most of the revenue, and how exposed is the business if they leave?
- Who has stopped buying without anyone noticing?
- How long does a customer typically take to place a second order, and is the business doing anything in that window?
- What proportion of customers ever buy twice?

On marketing

- Once a group worth contacting has been identified, how do you actually reach them without exporting a spreadsheet and hand-typing numbers?
- Which channel brings genuinely new customers, as opposed to capturing demand that already existed?
- What does each channel actually return, per customer rather than per click?
- Are the discount codes profitable, or are they discounting sales that would have happened anyway?

On stock

- Which products will run out before the next delivery lands?
- How much revenue is at risk if a best-seller stocks out?
- Which products are tying up capital in months of unnecessary cover?

On the future

- What is next month likely to look like, and is the store pacing ahead or behind?

Every one of these requires computation across the full order history. None can be read off a WooCommerce screen.

Why the usual alternatives do not fit

Manual spreadsheet exports. Stale the moment they are produced, and they put the analytical work on whoever has least time for it.

General business-intelligence tools. Capable, but someone has to model WooCommerce's database before a single question is answered. At this size the setup cost usually exceeds the value.

Hosted analytics services. Convenient, but they copy the entire order history, including customer names, email addresses, and postal addresses, onto a third party's servers. That is a data-protection question before it is a cost question.

Analytics plugins. They run heavy queries against the same database that serves the storefront, which is a reliable way to slow a shop down.

Why PulseCommerce

Against the tools already in place

Capability	PulseCommerce	WooCommerce Analytics	Google Analytics
Customer segmentation	Yes	No	No
RFM analysis	Yes	No	No
Customer lifetime value	Yes	No	No
Churn prediction	Yes	No	No
Inventory analytics	Yes	Basic	No
WhatsApp campaigns	Yes	No	No
Customer profiles	Yes	No	No
Forecasting	Yes	No	No
Self-hosted option	Yes	No	No
One-time purchase	Yes	No	No

Against the WhatsApp platforms

Capability	PulseCommerce	AiSensy	WATI	WooCommerce Reports
Customer analytics	Yes	No	No	Basic
RFM segmentation	Yes	No	No	No
Churn prediction	Yes	No	No	No
Inventory analytics	Yes	No	No	Basic
WhatsApp campaigns	Yes	Yes	Yes	No
Shared inbox	Yes	Yes	Yes	No
Forecasting	Yes	No	No	No
Customer lifetime value	Yes	No	No	No
Self-hosted option	Yes	No	No	No

The messaging platforms send well and know nothing about your customers. The analytics tools know your customers and cannot message them. This does both, which is the point: an audience defined by churn risk or by what someone bought can be messaged without leaving the screen it was defined on.

What the market charges monthly

Platform	Starting price	On top of that
AiSensy	₹1,500 per month	Meta message charges
Gallabox	approximately ₹2,399 per month	Meta message charges
Interakt	approximately ₹2,799 per month	Meta message charges
WATI	approximately \$39 per month (₹3,300+)	Meta message charges
Gupshup	Custom pricing	Meta message charges

Every one of these is a subscription that continues for as long as it is used, and none of it covers what Meta charges per conversation.

Feature comparisons and prices above reflect publicly available information at the time of writing. Third-party products and pricing change; verify before relying on any of it.

Proposed solution

A private analytics platform, running on infrastructure Nature's Joy controls, reading the store through WooCommerce's official REST API.

Four principles shape it.

It reads; it writes one thing

The platform reads orders, customers, and products, and nothing about that changes your store.

There is exactly one exception, and it exists because it was asked for: creating discount coupons for WhatsApp campaigns. WooCommerce offers no permission narrower than "read and write", so the restriction is enforced in the software instead — one function in the codebase creates a coupon, and no path anywhere modifies an order, a product, a customer, or a store setting.

If coupon creation is not wanted, the access can be reduced to read-only in a single line and re-approved; every other capability is unaffected.

No secrets change hands

Access is approved inside your own WordPress admin. WooCommerce issues the key and delivers it directly to the application. There is deliberately no form in the product that accepts a key by hand, because a merchant pasting a secret into a third party's form is the exact risk that approval flow exists to remove.

Your data stays yours

The application runs on your hosting. The key is held in your storage. Order data is cached in your infrastructure. Nothing is transmitted to any third-party analytics service.

Honest numbers

Where a figure is an estimate, the interface says so. Where a definition could be read two ways, both are reported and labelled rather than silently merged. Every metric definition is documented so figures can be reconciled against WooCommerce rather than taken on trust.

Proposed scope

Thirteen modules.

1. Revenue and performance

Net revenue, gross revenue, orders, average order value, units sold, discounts given, shipping and tax collected, refunds, items per order, revenue per customer, and cancellation rate. Every figure compared against the equal-length preceding period. Daily, weekly, or monthly views. Written findings ranked by urgency, in plain language.

2. Customer analytics

- **RFM segmentation** across the ten standard segments, from Champions to Lost, scored as quintiles within your own customer base so segments stay meaningful as the store grows
- **Value tiers** from VIP through to one-time buyers
- **Predicted lifetime value** per customer
- **Churn risk**, judged against each customer's own reorder rhythm rather than a fixed rule, so a monthly buyer and a seasonal buyer are assessed correctly
- **Revenue concentration**: deciles, Pareto curve, and a Gini coefficient quantifying how exposed the business is to losing its best customers
- Filtering on segment, tier, spend, order count, churn risk, recency, country, and product purchased
- A complete customer ledger, with each customer's orders expandable in place

3. Customer profiles

Every customer opens to a full profile: contact details, location, the channel and device they arrived through, RFM scores, revenue percentile, refunds, discounts used, what they buy, order value over time, and complete order history.

4. Acquisition and retention

- New versus returning revenue by month, with full customer lists for each
- **Channel attribution** using WooCommerce Order Attribution: organic search, direct, referral, paid, and campaign traffic
- Which channels bring genuinely first-time buyers rather than repeat demand
- Device breakdown by revenue and average order value
- **Time to second order**, with median, quartiles, and distribution, which identifies the window a follow-up should target

- **Cohort retention:** monthly acquisition cohorts tracked over time
- **Cumulative lifetime-value curve**, showing when an acquired customer pays back

5. Campaigns and audiences

- An **audience builder** with goal-driven presets: win-back lapsed customers, convert one-time buyers to a second order, rescue at-risk high-value customers, reward loyal advocates
- Live reach, revenue represented, and value at stake as filters are applied
- **CSV export** shaped for direct import into an email or advertising platform
- **Campaign performance** from UTM tagging, including new-customer share, which is the number that matters for paid acquisition
- **Coupon performance**, reporting revenue returned per unit of discount given

6. WhatsApp campaigns and automated flows

Reaching an audience directly, from the same place it is defined — once, or as a sequence that runs itself over days.

- Send a **text, image, or video** message to any audience built above
- **Nine ready-made templates**, each written for a specific job: reorder the product they buy, announce arrivals in a category they shop, win back a lapsed customer, convert a one-time buyer, thank a high-value customer, request a review, offer a discount with or without a product, or a plain announcement
- **Personalisation from each customer's own history** — their name, the product they have spent the most on, a link to it, its category, when they last ordered, how many times they have ordered, and what they have spent
- **Per-customer product photographs**, so each recipient sees the item they actually buy rather than a generic image
- **Product search**, to build a campaign around one specific item instead
- **Discount coupons:** use an existing WooCommerce coupon, or create one from the campaign screen with an expiry date, a limit of one use per customer, and a restriction to the product being promoted. Codes that have expired or reached their limit cannot be selected, so a customer is never sent a code that will be refused at the checkout
- A **dry run** that resolves the exact recipient list and sends nothing: how many are reachable, how many were excluded and for what reason, and the message exactly as the first recipient would receive it
- A **test send** to a number entered by hand, which cannot reach a customer
- **Confirmation of the recipient count** before a send begins, re-checked against the live audience at the moment it starts
- An **opt-out list** applied after the audience is built, so a filtering mistake cannot route around it

- **Paced delivery** with natural spacing, run as a resumable job with live progress and a stop control, which recovers by itself if the gateway restarts part-way through

How it connects. Messages are sent through a WhatsApp gateway running on infrastructure Nature's Joy controls. Customer numbers are never transmitted to a third-party messaging service, and never leave the server: the interface works with counts and reachability, and numbers are resolved only at the moment a message is sent.

What this requires. The gateway is a continuously running service and needs a small server of its own — shared web hosting cannot keep a WhatsApp connection alive. Setups Works can provide and manage this, or deploy it on infrastructure Nature's Joy already has.

A note on the risk. This uses a self-hosted gateway rather than Meta's official WhatsApp Business API. It avoids per-message fees and message template approval, but the number used carries a risk of restriction by WhatsApp, so a dedicated number should be used rather than the main business line. Tappable buttons and product cards are not available on this route; they are a feature of the official API. If guaranteed delivery or buttons matter more than cost, the official API is the alternative and can be quoted separately.

The nine templates

Template	What it says	When to send it
Reorder	Names the product they bought, links straight to it	Their usual reorder gap has passed
Category arrivals	New items in the range they already shop	You add stock to a category
Win back	References their product and when they last ordered	At Risk or Hibernating customers
Second order	Asks how they got on, invites a repeat	One-time buyers, still recent
VIP thank you	Names their order count, invites a reply	Champions and top-tier customers
Review request	Asks for feedback on what they actually buy	Repeat customers with a recent order
Coupon and product	A discount tied to their own product	Lapsed customers worth converting
Coupon only	A store-wide discount offer	Any audience with no clear favourite
Announcement	Your own words, with the greeting still personal	News, opening hours, anything else

Templates are edited freely before sending. No approval process applies, unlike Meta's official API.

The ten variables

Each resolves from that customer's own order history at the moment of sending:

Variable	Becomes, for one customer
name	Priya
product	Manjistha Soap
product_url	The buy link for that product
category	Herbal Soaps
last_order	14 March
orders	7
spend	₹4,180
store	Nature's Joy
coupon	SAVE10NOW
coupon_value	10% off

The product chosen is the one they have spent the most on, not their most recent purchase — a one-off small order should not become the thing a reorder message is built around. A variable with no value for someone is removed and the sentence tidied afterwards, so nobody receives a literal placeholder or a dangling comma.

Discount coupons

Coupons are created in WooCommerce directly from the campaign screen, so the code exists in your store the moment it is generated. Each is limited to one use per customer, expires on a date you set, and — when a campaign product is chosen — is restricted to that product so a discount meant for one item cannot be spent across the catalogue. Generated codes avoid the characters O, 0, I and 1, because they are read off a phone screen and typed at a checkout.

Codes that have expired or reached their usage limit are shown but cannot be selected. Sending a code that will be refused at the checkout is worse than sending none at all.

Coupon performance is reported back: uses, discount given, revenue produced, and return on discount — so you can see whether an offer bought incremental orders or simply discounted sales that would have happened anyway.

How a large send actually runs

Messages go out roughly four seconds apart with random variation, in batches of a hundred handed to the gateway at a time. A campaign to the full customer base therefore runs for hours rather than minutes, which is deliberate: sending thousands of messages in a short window is the single most reliable way to have a WhatsApp number restricted.

The send is a resumable job. Closing the page pauses it rather than breaking it, anything already handed over still goes out, and reopening continues from where it stopped. If the gateway's own process restarts part-way through, the platform detects it and reconnects by itself rather than failing the remaining recipients.

Every excluded recipient is counted and categorised — no phone number on file, a number that cannot be read, a duplicate shared with another record, or someone on the opt-out list — so a result of "sent 9,800 of 11,224" always has an explanation.

Automated flows

A campaign is one message, now. A flow is a sequence that runs itself over days, so a customer receives the right message at the right point rather than whenever somebody remembered to send one.

- **Multi-step sequences** — up to ten messages, each waiting a set number of days after the one before it
- **Customers join as they qualify.** The audience is re-checked on every run, so a customer who lapses next month enters the win-back sequence next month. A flow keeps working rather than sending once to whoever matched on the day
- **Nobody enters twice**, for the life of the flow
- **They leave the moment it works.** With "exit when they order" set, a customer who buys stops receiving the rest of the sequence. A win-back that keeps nagging someone who already came back is worse than not running at all
- **A test number**, so a whole sequence can be checked on your own phone before a customer ever sees it. A flow built as a test cannot later be pointed at an audience by mistake
- **Created as a draft.** Designing a sequence and starting to send it to thousands of people are two separate decisions
- **Steps are fixed once it runs.** People are already part-way through, and changing a later step under someone who has had the earlier ones would give them a sequence nobody designed

Timing is honest rather than approximate. Each wait is measured from when the previous message actually sent, so a delayed run never bunches two messages together. A run that is missed delays a step; it cannot lose one, and it cannot send one twice.

7. Shared WhatsApp inbox and automatic replies

Replies to a campaign land somewhere the business can see them, alongside who sent them — and a customer who writes out of hours is answered immediately.

- Every conversation shown with **the customer behind the number**, not a bare phone number, together with how many times they have ordered and what they have spent
- One click through to that customer's full profile and order history
- Replies arrive without a page refresh
- Send **text, an image or video, or a product from the catalogue** in reply
- **Start a conversation from a phone number**, without waiting to be messaged first
- Unread counts and search across names and numbers
- The opt-out list applies here too: someone who asked the business to stop is not messaged, whether by a campaign or by hand

Answering before anyone is at a desk

A customer who messages the business out of hours currently waits until morning. An optional menu answers immediately.

- A customer sends an agreed word — **"hi"** — and receives a numbered menu: order, contact, feedback
- Their reply selects an option, and menus can nest as deeply as needed
- Each conversation remembers where it is, and forgets after fifteen minutes, so a stray number the next day is never read as a menu choice
- **Only the trigger word starts it.** Anything else is left for a person to answer, so the menu never intercepts a real question
- Runs on the gateway itself, which means it answers at three in the morning whether or not anything else is running

The value is context. Answering "is this back in stock?" is a different conversation when the person asking has ordered eleven times.

8. Product and catalogue analytics

ABC classification identifying which products carry the revenue, Pareto concentration, revenue and units per SKU, refund rate per product, category mix, best sellers by both value and volume, slow movers, and market-basket analysis showing which products genuinely sell together.

9. Inventory and restock planning

- **Days of cover** per product, from current stock and observed sales velocity
- **Reorder points** calculated from your supplier lead time plus safety stock

- **Suggested order quantities** to reach a healthy cover level
- **Revenue at risk** if a fast-moving product stocks out
- **Capital tied up** in products carrying excessive cover
- Exports as a **draft purchase order**
- Every assumption shown on screen and adjustable to your actual supplier terms

10. Orders and operations

Full order register with totals, tax, shipping, discounts, refunds, payment method, and coupons. Order status mix, basket-size distribution, payment method performance, a day-by-hour trading heatmap for timing campaigns and staffing, weekday performance, and fulfilment timing.

11. Forecasting

Daily revenue projection combining trend with day-of-week seasonality, presented with a 95% confidence band. The seasonality is shown explicitly so the projection can be sense-checked rather than accepted blindly.

12. Geography

Revenue, orders, customers, and average order value by country, region, and city.

13. Reports and exports

- Ten report types covering every module
- **Excel** workbooks with formatted sheets, filters, and correct currency formatting
- **PDF** reports with a cover, headline figures, and findings
- **CSV** for spreadsheets and data pipelines
- Presets for a board pack, CRM upload, merchandising review, and finance reconciliation
- A **written report view** presenting a period as a document: conclusion first, evidence below, method and limits at the end

Platform capabilities

Support for connecting more than one store and switching between them, a search palette covering customers, products, and orders, keyboard navigation, light and dark themes, and optional password protection.

A documented interface. Every endpoint the platform exposes is described in a published specification and browsable in the application itself, so a future developer — or another system of yours — can work against it without reading the source. An automated check fails the build if a route exists that the documentation does not describe, which is what keeps it true over time.

An extendable gateway. The private gateway option supports installed extensions, ten of which are available and already in place: the menu bot described above, an after-hours auto-reply, an FAQ responder, voice-note transcription, group translation, logging to Google Sheets, and connectors for Chatwoot, Typebot and Supabase. Each is off until deliberately switched on and configured, and each can be removed again. Nothing here is a further cost from us; they are listed so the ceiling is visible.

How it is built

Three separate pieces, only one of which is the application.

One pull, then everything. Metrics like cohort retention and lifetime value need the whole order history, not a page of it. The platform pulls once, caches the result, and computes every figure from that cache — which is why changing a date range is instant rather than another wait on the store.

The storefront is never in the path. Analysis runs against the cached copy, so no customer ever waits on a query the business is running.

Numbers stay on the server. The browser receives names and counts. Phone numbers are resolved only at the moment a message is sent, which means a mistake in the interface cannot expose the customer list.

Sending is resumable. A campaign to a large audience takes hours at a safe pace. It runs as a job that records its position, so closing the page pauses it rather than losing it, and a restart of the gateway costs a short delay rather than the remainder of the audience.

Waiting is resumable too. A flow spends most of its life between steps, which no web request can sit through. A scheduled job runs each day and works out what is due from the record rather than from having been running at the right moment. Nobody needs a browser open, and an interruption delays a message rather than losing it.

How access works

1. You enter your store address in the application.
2. You are sent to your own WordPress admin, where you review and approve **read-only** access.
3. WooCommerce issues a key and delivers it directly to the application.
4. The application verifies the key against the store before storing it.

No password is shared. No key is emailed. Access can be revoked at any time, either from within the application or from WordPress itself. Disconnecting removes the stored key and every cached order.

Deliverables

1. **The platform**, covering the thirteen modules above, including automated multi-step flows and the out-of-hours menu bot.
2. **Source code**, in a repository Nature's Joy owns.
3. **Deployment** to the agreed hosting, configured and verified against the live store.
4. **Documentation** covering setup, connection, configuration, architecture, and troubleshooting.
5. **Metric definitions in writing**, so every figure can be reconciled against WooCommerce.
6. **Handover session** covering day-to-day use and how to read each module.

Hosting options

Managed by Setups Works. Hosting, monitoring, and updates handled on your behalf, including the WhatsApp gateway. Nothing for your team to operate.

Nature's Joy infrastructure. Any host running Node. Best performance, as the data cache persists between requests.

Serverless. Lowest operational overhead, using a managed cache. Suitable for most catalogue sizes.

Commercial terms

Two routes. They deliver the same thirteen modules, the same deployment, documentation, handover and source code. They differ in one thing: whether you keep paying to send messages.

	Private WhatsApp gateway	WhatsApp Cloud API
One-time fee	₹35,000	₹25,000
Then	Nothing	≈ ₹10,000 every month
Cost per message	None	Charged by Meta, per conversation
Message templates	Written and sent immediately	Require Meta's approval first
Delivery	Not guaranteed	Guaranteed by Meta
Tappable buttons	Not available	Available
Running cost	Server hosting, ≈ ₹500 per month	Meta's per-conversation charges
Setup	Scan a QR code	Meta Business verification

What “≈ ₹10,000 every month” means

The ₹25,000 fee covers the platform. The messages themselves are billed by Meta, per conversation, and that charge never stops.

One campaign a month to your 11,224 customers costs roughly ₹10,000 at current marketing rates — approximately ₹1,20,000 a year, paid to Meta rather than to Setups Works. Send more often and it rises proportionally.

Meta sets these rates, varies them by country and message category, and changes them without notice. The figure above is an illustration at roughly ₹0.89 per marketing conversation and should be confirmed against Meta's published pricing.

What the private gateway costs to run

Nothing per message. The ₹35,000 covers the platform and a dedicated WhatsApp messaging server on infrastructure Nature's Joy controls. The only running cost is that server, approximately ₹500 a month, billed by your hosting provider.

Three years, compared

One campaign a month to 11,224 customers, with Meta charges at approximately ₹10,000 a month for every route that pays them:

Route	Fee or subscription	Meta charges	Three-year total
AiSensy	₹54,000	₹3,60,000	₹4,14,000
Gallabox	₹86,364	₹3,60,000	₹4,46,364
Interakt	₹1,00,764	₹3,60,000	₹4,60,764
WATI	₹1,18,800	₹3,60,000	₹4,78,800
PulseCommerce + Cloud API	₹25,000 once	₹3,60,000	₹3,85,000
PulseCommerce + private gateway	₹35,000 once	₹0	₹53,000

Against the cheapest subscription platform, the private gateway saves approximately ₹3,61,000 over three years. The saving is not the build fee. It is the per-message charge ceasing to apply.

What is not in this price

The fee covers the thirteen modules described in this document and nothing beyond them. Anything additional is quoted separately before any work on it begins, so there are no unexpected charges:

Additional work	How it is charged
A new module not listed in the thirteen	Quoted per module, on scope
Custom metrics or reports specific to your business	Quoted on scope
Integrations with other systems — ERP, courier, accounting	Quoted on scope
Scheduled or automated campaign triggers	Quoted on scope
Ongoing support and maintenance	Monthly retainer, agreed separately
Managed hosting of the platform or gateway	Monthly, agreed separately
Changes requested after handover	Day rate, agreed separately

Nothing in this list is required for the platform to work. Every one of them is optional, and none will be started without a written quotation you have accepted.

Payment schedule: to be agreed in writing before work commences.

Timeline: to be confirmed on acceptance.

Validity: this quotation is valid for 30 days from the date of issue.

Optional extensions

Available separately, either at the outset or later.

- **Scheduled reports** delivered by email weekly or monthly
 - **Stock alerts** when a product crosses its reorder point, so a fast-moving product cannot run out unnoticed
 - **Direct email-platform integration**, so audiences sync automatically rather than being exported and imported
 - **Official WhatsApp Business API**, in place of the self-hosted gateway, where guaranteed delivery is worth per-message fees and template approval
 - **Profitability analysis**, given cost-of-goods data, turning revenue figures into margin
 - **Multi-currency consolidation**, should trading extend beyond INR
 - **Additional stores**, supported by the platform without further development
-

Next steps

1. Review the scope above and confirm which modules and options are wanted.
 2. Agree commercial terms and schedule.
 3. **Walkthrough.** On acceptance, Setups Works will demonstrate the platform against Nature's Joy data so the findings can be seen before rollout.
 4. Deployment, verification, and handover.
-

Appendix: complete feature list

Everything included in the thirteen modules, listed so nothing delivered goes unmentioned.

Revenue and performance. Net and gross revenue, orders, average order value, units, discounts, shipping, tax, refunds, items per order, revenue per customer, cancellation rate, period-on-period comparison, daily, weekly and monthly views, sparkline trends, and written findings ranked by urgency.

Customer analytics. RFM scoring, ten segments, five value tiers, predicted lifetime value, churn risk, revenue deciles, Pareto curve, Gini coefficient, recency-frequency plot, top-customer spotlight, ready-made high value, low value, at risk and rising cohorts, and a complete ledger with orders expandable in place.

Customer profiles. Contact details, location, acquisition channel and device, RFM scores, revenue percentile, refunds, discounts used, what they buy ranked by revenue, order value over time, and full order history.

Acquisition and retention. New versus returning revenue, full customer tables, channel attribution, first-time buyer analysis by channel, device breakdown, pages per session, time to second order with quartiles, monthly cohort retention, the cumulative lifetime value curve, and attribution coverage.

Campaigns and audiences. Audience builder with live reach, six goal presets, filters on segment, tier, recency, spend, order count, churn risk, country, account type, product purchased and contactability, revenue and predicted value at stake, CSV export for email and advertising platforms, campaign performance from UTM tags, and coupon return on discount.

WhatsApp campaigns. Text, image and video messages, nine templates, ten personalisation variables, per-customer product photographs, catalogue product search, coupon creation and attachment, dry run, test send, typed confirmation, opt-out list, paced sending with variation, resumable jobs, automatic recovery, live progress and a stop control.

Shared inbox. Conversations matched to customers, order count and lifetime spend beside each, link to the full profile, live reply polling, text, media and product replies, starting a conversation from a number, unread counts, search across names and numbers, and opt-out enforcement.

Product and catalogue analytics. ABC classification, Pareto concentration, revenue, units, orders and distinct customers per product, average price and velocity, refund rate per product, average rating, market-basket affinity by lift, category mix, best sellers by value and volume, slow movers and never-sold items.

Inventory and restock planning. Days of cover, reorder points from your supplier lead time, suggested order quantities, out of stock, critical, low, healthy and overstocked states, revenue at risk, capital tied up, a restock planner, and a draft purchase order export.

Orders and operations. Full order register, status mix, basket-size distribution, payment method performance, a day-by-hour trading heatmap, weekday performance and fulfilment timing.

Forecasting and geography. Daily revenue projection, 95% confidence band, weekday seasonality shown explicitly, and revenue, orders, customers and average order value by country, state and city.

Reports and exports. Ten report types, Excel with formatted sheets, filters and currency formats, PDF with cover, headline figures and findings, CSV for spreadsheets and pipelines, presets for a board pack, CRM upload, merchandising review and finance reconciliation, a written report view, and exports that match the on-screen date range without truncation.

Platform. Multiple stores with instant switching, a command palette across customers, products and orders, keyboard navigation throughout, light and dark themes, persisted date ranges, sortable, searchable and expandable tables, optional password protection, honest empty states, and partial-data warnings surfaced rather than hidden.

Security. Approval inside your own WordPress admin, no credential ever typed into a form in this product, verification before saving, keys shown only masked, customer phone numbers never sent to the browser, opt-outs enforced on the server, and a one-click disconnect that wipes the stored key and every cached order.

Appendix: how key figures are defined

Included so that, once delivered, every number can be reconciled against WooCommerce rather than taken on trust. These are the definitions where analytics tools most often disagree with each other.

Net revenue. Order total less tax, shipping, and refunds, counted only for orders in completed, processing, or on-hold status. Cancelled, failed, and pending orders are excluded from revenue while still counting toward cancellation rates.

Customer identity. Guest checkouts carry no WooCommerce customer ID, so buyers are identified by billing email address. A customer ordering under two different email addresses will appear as two customers. On most stores the majority of orders are guest checkouts, so this materially affects customer counts and should be understood when reading them.

Returning customer rate. The share of customers active in a period who had already purchased before it began.

Repeat rate in period. The share of customers who purchased more than once inside the period itself. On a short window this differs from the returning customer rate by a wide margin. Both are reported separately and labelled, because conflating them is a common source of misleading retention figures.

RFM scores. Recency, frequency, and monetary values scored as quintiles within the store's own customer base rather than against absolute thresholds, so segments remain meaningful regardless of the store's size.

Predicted lifetime value. Each customer's observed purchase rate projected twelve months forward, discounted by their churn risk. An estimate, and presented as one.

Days of cover. Current stock divided by units sold per day over the selected period. Reorder points add a supplier lead time and a safety-stock buffer, both configurable to your actual terms.

Forecast. A least-squares trend multiplied by day-of-week seasonality factors, with a 95% interval derived from historical variance. It answers whether the store is pacing ahead of or behind its recent trend. It has no knowledge of planned promotions, stockouts, or seasonality outside the period analysed.

Terms and conditions

About the figures

All store figures in this document were computed from naturesjoystore.com covering 1 August 2025 to 31 July 2026, across 20,444 orders retrieved through the WooCommerce REST API. Figures change as the store trades and should be re-run before being relied upon.

Net revenue is order total less tax, shipping and refunds, counting only orders in completed, processing or on-hold status. Cancelled, failed and pending orders are excluded from revenue but included in cancellation rates. This may differ from figures shown elsewhere in WooCommerce, which counts differently.

Guest checkouts carry no WooCommerce customer identifier, so buyers are identified by billing email address. One person ordering under two email addresses counts as two customers, which affects customer counts and repeat rates.

About projections

Win-back revenue, campaign returns, break-even points and forecasts are illustrations based on stated assumptions. They are not forecasts, guarantees, warranties or commitments of any kind, and actual results will differ, potentially materially.

Predicted lifetime value and churn risk are estimates derived from observed purchase behaviour. Forecasts use a least-squares trend with day-of-week seasonality and have no knowledge of planned promotions, stock availability, price changes or seasonality outside the period analysed.

Days of cover and revenue at risk are calculated from observed sales velocity and current stock levels where WooCommerce tracks them. Products without stock management enabled cannot be planned for.

About WhatsApp delivery

Messaging uses a self-hosted gateway connecting through unofficial, reverse-engineered clients rather than Meta's official WhatsApp Business API. Message delivery is not guaranteed.

WhatsApp may, at its sole discretion and without notice, restrict, suspend or permanently ban any number used for automated messaging. No appeal route exists through this software or through Setups Works. A number reserved for this purpose must be used, never the primary business line. Setups Works accepts no liability for the restriction, loss or suspension of any number, for messages that fail to deliver, or for consequential business loss arising from either.

Tappable buttons and product cards are features of Meta's official API and cannot be delivered by a self-hosted gateway. They are excluded from this scope.

You are responsible for ensuring messages sent comply with applicable law, including consent, data protection and unsolicited-communication rules in the recipient's jurisdiction, and with WhatsApp's own terms. The opt-out list is provided as a tool; honouring requests to stop remains your obligation.

About third-party costs

WhatsApp Cloud API rates are set by Meta, vary by country and message category, and change without notice. Any rates shown are illustrative ranges rather than quotations; confirm current pricing with Meta before making a decision on that basis.

Server hosting for the WhatsApp gateway, estimated at approximately ₹500 per month, is billed by your hosting provider and is not included in the quoted price. A dedicated phone number for WhatsApp sending is also not included. Domain, SSL and WooCommerce hosting remain your existing arrangements.

The WhatsApp gateway is independent open-source software provided under its own licence and maintained by its own authors. Setups Works does not control its development, its availability, or its continued compatibility with WhatsApp.

About your data

All store and customer data remains the property of Nature's Joy and stays on infrastructure you control. No data is transmitted to Setups Works or to any third-party analytics or messaging service.

Store access is read-only with a single exception: creating the discount coupons you request. Nothing modifies an order, a product, a customer or a store setting. Access can be revoked at any time from WordPress without notice to us.

About this quotation

The quoted fee covers the build, deployment, configuration, documentation and handover of the thirteen modules described in this document. Source code is delivered to a repository owned by Nature's Joy. Work outside this scope, including additional modules, custom metrics, integrations or ongoing support, is quoted separately.

This quotation is valid for 30 days from the date of issue. Payment terms to be agreed in writing before work commences.
