Prepared for Nature's Joy

Nature's Joy Herbal Cosmetics Private Limited naturesjoystore.com

Prepared by **Nitheesh Rajendran**, Setups Works setups.works

What this is

PulseCommerce is an analytics platform built for your WooCommerce store. It is already built, already deployed, and already connected to naturesjoystore.com.

This proposal is not a pitch for something that might be made. It is a summary of a working system, the findings it has already produced from your own orders, and the terms on which it can be handed over and supported.

Everything in this document was measured against your live store: 20,490 orders, 11,286 customers, and your full catalogue, covering trading from 23 August 2025 to 1 August 2026.

What it found in your store

Before describing features, here is what the system reported from your own data on the most recent 30-day window. These are not illustrations. They are the current state of the business.

Inventory is the most urgent finding

Seven products will run out within three weeks at current sales velocity.

Product	Days of cover	Suggested order
Manjistha Soap	7	1,652 units
Manjistha With Goat Milk Soap	8	762 units
Nalangu Maavu Soap (Women)	10	594 units
Goat Milk Soap	12	209 units

Manjistha Soap is your single largest product. It generates ₹2,00,808, which is **31.7% of all product revenue**, and it currently has roughly **seven days of stock left**. On a fourteen-day supplier lead time, that is already late to reorder.

Across the products running low, the system estimates **₹93,703 of revenue at risk** over one lead time if nothing is ordered.

At the same time, **five products are carrying more than six months of cover**. BIO ENZYME LAUNDRY WASH holds 683 days of stock. Total stock value sits at ₹3,07,670, and a meaningful share of that is capital doing nothing.

This one module, on its own, is the difference between a stockout on your best seller and a purchase order placed in time.

Revenue is concentrated in very few products

Eight SKUs generate 80% of product revenue, out of forty that sold. The rest is a long tail worth reviewing for pruning or promotion.

Customer retention is the biggest structural opportunity

- **Only 4.9% of customers ordered more than once** in the window. 95.1% bought exactly once.
- **817 customers, together worth ₹3,91,288, are showing churn signals**, meaning they have gone quiet well past their own usual reorder gap.
- The **median time to a second order is 11 days**. That is the window a well-timed follow-up should target, and it is short.

Your top 10% of customers drive 27.4% of revenue, with a Gini coefficient of 0.36. Revenue is reasonably spread rather than dangerously concentrated, which means the opportunity is in converting one-time buyers, not in protecting a handful of accounts.

Where your customers actually come from

Channel	Revenue
Organic search (Google)	₹3,13,800
Paid, Instagram	₹1,38,656
Direct	₹1,26,122

93.8% of revenue comes from mobile. Desktop is 6.2%.

Your `first10` coupon returned **9.0x the discount given** across 95 redemptions, which is a strong result and worth knowing before deciding whether to keep it.

Current trading

Net revenue for the window is ₹6,32,689 across 1,327 revenue-bearing orders from 1,263 customers, at an average order value of ₹477. That is **down 7.7% against the preceding 30 days**. Saturday is the strongest trading day. The system projects ₹2,10,568 over the next fourteen days.

Why WooCommerce alone does not show this

WooCommerce reports on orders. It does not report on customers, cohorts, channels, or stock risk.

None of the findings above are visible in the WooCommerce admin without exporting data and analysing it by hand. Days of cover, churn signals, time to second order, channel attribution, and product concentration all require computation across the full order history, which is exactly what this system does.

The practical alternatives each have a cost:

- **Manual spreadsheets** are stale the moment they are produced.
 - **General BI tools** need someone to model WooCommerce's schema first, which usually costs more than the answer is worth at this size.
 - **Hosted analytics services** copy your entire customer list, including names, emails, and addresses, to a third party.
 - **Plugins** run analytical queries against the same database serving your storefront, which slows the shop down.
-

How it connects to your store

Read-only, by construction. Only GET requests, and only to orders, customers, and products. The key WooCommerce issues carries read scope. There is no code path by which this system can modify your store, change an order, or touch a product.

You never hand over a password or a secret. You approve access inside your own WordPress admin. WooCommerce issues the key and delivers it directly to the application. There is deliberately no form anywhere in the product that accepts a key, because a merchant pasting a secret into someone else's form is the risk that flow exists to remove.

Nothing leaves your infrastructure. The application runs on hosting you control. The key is stored in your storage. Order data is cached in your infrastructure. No customer data is transmitted to any third party.

Revocable in one click. Disconnecting removes the stored key and every cached order. You can also revoke the key from WordPress at any time.

What the system does

Eleven modules, all built and running against your store today.

Revenue and performance

Net revenue, gross revenue, orders, average order value, units, discounts, shipping, tax, refunds, items per order, revenue per customer, and cancellation rate. Every figure compared against the equal-length preceding window. Daily, weekly, or monthly views. Written findings ranked by urgency.

Customer analytics

RFM scoring across ten standard segments, computed as quintiles within your own customer base. Value tiers from VIP to one-time. Predicted lifetime value per customer. Churn risk judged against each customer's own reorder cadence rather than a fixed rule. Revenue deciles, Pareto curve, and Gini concentration. Filtering on segment, tier, spend, orders, churn risk, recency, country, and product bought. Full ledger of all 11,286 customers with orders expandable in place.

Customer profiles

Every customer drills through to a profile: contact details, location, acquisition channel and device, RFM scores, revenue percentile, refunds, discounts used, what they buy, order value over time, and complete order history.

Acquisition and retention

New versus returning revenue by month with full customer lists for each. Channel and device attribution from WooCommerce Order Attribution. Which channels bring genuinely first-time buyers rather than repeat demand. Median time to second order with a distribution. Monthly cohort retention triangle and a cumulative lifetime-value curve.

Campaigns and audiences

An audience builder with goal-driven presets: win-back lapsed, convert to second order, rescue at-risk high value, VIP appreciation, loyal advocates. Live reach and revenue at stake as filters are applied. Exports a CSV shaped for import into an email or advertising platform. Campaign

performance from UTM tagging, and coupon return on discount.

For Nature's Joy specifically, the win-back audience currently holds 817 customers worth ₹3,91,288.

Product and catalogue analytics

ABC classification, Pareto concentration, revenue and units per SKU, refund rate per product, category mix, best sellers by value and volume, slow movers, and market-basket affinity showing which products genuinely sell together.

Inventory and restock planning

Days of cover per SKU, reorder points from a stated lead time plus safety stock, suggested order quantities, revenue at risk from stockouts, and capital tied up in overstock. Exports as a draft purchase order. Every assumption is shown on the page and adjustable to your real supplier terms.

Note: WooCommerce is currently tracking stock for 17 of your 40 selling SKUs. Enabling stock management on the remainder would extend this module to the whole catalogue.

Orders and operations

Full order register with totals, tax, shipping, discount, refunds, payment method, and coupons. Status mix, basket-size distribution, payment method performance, a day-by-hour trading heatmap, weekday performance, and fulfilment timing.

Forecasting

Daily revenue projection from trend and day-of-week seasonality, with a 95% confidence band. Weekday seasonality is shown explicitly so the projection can be sense-checked rather than taken on trust.

Geography

Revenue, orders, customers, and average order value by country, region, and city.

Reports and exports

Ten report types, exportable as a formatted Excel workbook, a typeset PDF, or raw CSV. Presets for a board pack, a CRM upload, a merchandising review, and finance reconciliation. Exports always match the range on screen and are never truncated. A written report view presents the same period as a document: conclusion first, evidence below, method and limits at the end.

Platform

Multiple stores can be connected and switched between, each with its own credentials and cache. A command palette searches customers, products, and orders in one place. Keyboard navigation throughout. Light and dark themes. Optional password protection.

Performance

Measured against your store, not a benchmark.

Measure	Result
Orders analysed	20,490
Customers analysed	11,286
Cold load, empty cache	3.5 seconds
Warm request	0.7 seconds
Deployed production request	approximately 2 seconds
Full customer data, on the wire	911 KB

Reaching this took three specific pieces of work. Order payloads were trimmed of fields the system never reads, cutting transfer by 81%. The data snapshot was moved to shared caching, so a full re-pull happens once an hour rather than on every request. And order fetching was paced and bounded, because an earlier, more aggressive version generated enough sustained traffic that your store's own security layer began refusing it.

What is delivered

1. **The application**, complete, covering all eleven modules.
2. **Source code**, in a repository Nature's Joy controls.
3. **Deployment** to your chosen hosting, configured and verified against your live store.
4. **Documentation**: setup, connection, configuration, metric definitions, architecture, and troubleshooting.
5. **Metric definitions in writing**, so every figure can be reconciled against WooCommerce rather than taken on trust.
6. **Handover session** covering operation and how to read each module.

Hosting options

Managed by Setups Works. Hosting, monitoring, and updates handled for you. Nothing to operate.

Your own hosting. Any host that runs Node. Best performance, since the cache persists between requests.

Serverless. Lowest operational burden, with a managed Redis store. Cold starts re-pull data, so a persistent host is preferable given your catalogue size.

Commercial terms

Complete before sending. The figures below are placeholders.

Item	Scope	Fee
Implementation and handover	Deployment, connection, configuration, documentation, walkthrough	[amount]
Managed hosting	Hosting, monitoring, updates, per month	[amount]
Support	Agreed response times and hours, per month	[amount]
Further development	Custom modules or metrics, per day	[day rate]

Payment schedule: [for example, 50% on commencement, 50% on handover]

Timeline: The platform is built and already connected. Deployment to your chosen hosting and handover can be completed within [timeframe].

Recommended next steps

Independent of the commercial decision, three findings above are worth acting on this week.

1. **Place a purchase order for Manjistha Soap.** Seven days of cover on a product carrying 31.7% of your product revenue is the single largest near-term risk in the business.
2. **Run a win-back campaign** to the 817 lapsed customers worth ₹3,91,288. The audience exports as a CSV ready for your email platform.
3. **Target the second order.** With 95.1% of customers buying exactly once and a median 11 days to reorder, a follow-up timed to the second week is the highest available lever on life-time value.

To proceed with the platform itself:

1. Confirm scope and hosting preference.
 2. Agree commercial terms.
 3. Deploy and verify. Access is already authorized.
 4. Handover.
-

Optional extensions

Each can be scoped separately.

- **Scheduled reports** delivered by email weekly or monthly
 - **Stock alerts** when a product crosses its reorder point, so the Manjistha situation cannot recur unnoticed
 - **Direct email-platform integration**, so audiences sync rather than exporting
 - **Profitability analysis**, given cost-of-goods data, turning revenue into margin
 - **Multi-currency** if you begin trading outside INR
 - **Additional stores**, already supported by the platform
-

Appendix: how the figures are defined

Stated explicitly, so numbers can be reconciled against WooCommerce.

Net revenue. Order total less tax, shipping, and refunds, counted only for orders in completed, processing, or on-hold status. Cancelled, failed, and pending orders are excluded from revenue but still counted in cancellation rates.

Customer identity. Guest checkouts carry no WooCommerce customer ID, so buyers are identified by billing email. A customer ordering under two different email addresses appears twice. The large majority of your orders are guest checkouts, so this matters when reading customer counts.

Returning customer rate. Share of customers active in a period who had already purchased before it. Currently 43.2%.

Repeat rate in period. Share who purchased more than once inside the period. Currently 4.9%. Both are reported, separately and labelled, because on a 30-day window they differ by an order of magnitude and are routinely confused.

RFM scores. Quintiles within your own customer base, not absolute thresholds.

Predicted lifetime value. Each customer's observed order rate projected twelve months forward, discounted by churn risk. An estimate, and labelled as one.

Days of cover. Current stock divided by units sold per day over the selected range. Reorder points assume a fourteen-day supplier lead time plus seven days of safety stock. Both are shown on the page and should be adjusted to your actual supplier terms.

Forecast. Ordinary least squares on the level, multiplied by day-of-week factors, with a 95% band from in-sample residuals. It answers whether the store is pacing ahead or behind. It does not know about promotions, stockouts, or seasonality outside the selected window.

Figures in this proposal were measured from naturesjoystore.com on 1 August 2026, covering the 30 days to that date unless otherwise stated, against a full order history from 23 August 2025.
